

## 4 Fixed-Parameter Algorithms

- 4.1 Fixed-Parameter Tractability
- 4.2 Depth-Bounded Exhaustive Search I
- 4.3 Problem Kernels
- 4.4 Depth-Bounded Search II: Planar Independent Set
- 4.5 Depth-Bounded Search III: Closest String
- 4.6 Linear Recurrences & Better Vertex Cover
- 4.7 Interleaving

# Philosophy of FPT

- ▶ **Goal:** Principled theory for studying complexity based on two dimensions:  
input size  $n = |x|$  (encoding length) and *some additional parameter  $k$*
  - ▶ generalize ideas from  $k = \text{MaxInt}(x)$
  - ▶ investigate influence of  $k$  (and  $n$ ) on running time
- ↪ Try to find a parameter  $k$  such that
- (1) the problem can be solved efficiently as long as  $k$  is small, and
  - (2) practical instances have small values of  $k$  (even where  $n$  gets big).

# Motivation: Satisfiability

## Consider Satisfiability of CNF formula

- ▶ general worst case: NP-complete
- ▶  $k$  = #literals per clause
  - ▶  $k \leq 2 \rightsquigarrow$  in P
  - ▶  $k \geq 3$  NP-complete
- ▶  $k$  = #variables
  - ▶  $O(2^k \cdot n)$  time possible (try all assignments)
- ▶  $k$  = #clauses?
- ▶  $k$  = #literals?
- ▶  $k$  = #ones in satisfying assignment
- ▶  $k$  = structural property of formula
- ▶ for MAX-SAT,  $k$  = #optimal clauses to satisfy

*the drosophila melanogaster of complexity theory*

# Parameters

## Definition 4.1 (Parameterization)

Let  $\Sigma$  a (finite) alphabet. A *parameterization* (of  $\Sigma^*$ ) is a mapping  $\kappa : \Sigma^* \rightarrow \mathbb{N}$  that is polytime computable. ◀

## Definition 4.2 (Parameterized problem)

A *parameterized (decision) problem* is a pair  $(L, \kappa)$  of a language  $L \subset \Sigma^*$  and a parameterization  $\kappa$  of  $\Sigma^*$ . ◀

## Definition 4.3 (Canonical Parameterizations)

We can often specify a parameterized problem conveniently as a language of *pairs*  $L \subset \Sigma^* \times \mathbb{N}$  with

$$(x, k) \in L \wedge (x, k') \in L \rightarrow k = k'$$

using the *canonical parameterization*  $\kappa(x, k) = k$ . ◀

# Examples

As before: Typically leave encoding implicit.

## Definition 4.4 (p-variables-SAT)

Given: formula boolean  $\phi$  (same as before)

Parameter: number of variables

Question: Is there a satisfying assignment  $v : [n] \rightarrow \{0, 1\}$  ?

## Definition 4.5 (p-Clique)

Given: graph  $G = (V, E)$  and  $k \in \mathbb{N}$

Parameter:  $k$

Question:  $\exists V' \subset V : |V'| \geq k \wedge \forall u, v \in V' : \{u, v\} \in E$  ?

# Canonical Parameterization

## Definition 4.6 (Canonically Parameterized Optimization Problems)

Let  $U = (\Sigma_I, \Sigma_O, L, L_I, M, cost, goal)$  be an optimization problem.

Then  $p\text{-}U$  denotes the *(canonically) parameterized (decision) problem* given by the threshold problem  $Lang_U$ . 

**Recall:**  $Lang_U$  is the set of pairs  $(x, k)$  of all instances  $x \in L_I$  that have solutions that are weakly “better” than  $k$ .

Examples:

- ▶  $p\text{-CLIQUE}$
- ▶  $p\text{-VERTEX-COVER}$
- ▶  $p\text{-GRAPH-COLORING}$
- ▶ ...

**Naming convention** for other parameters:

$p\text{-}clause\text{-CNF-SAT}$ : CNF-SAT with parameter “number of *clauses*”

## 4.1 Fixed-Parameter Tractability

# Exemplary Running Times of Parameterized Problems

## ▶ $p$ -variables-SAT

(consider simplest brute-force methods for problems)

- ▶  $k$  variables,  $n$  length of formula

↪  $O(2^k \cdot n)$  running time

## ▶ $p$ -CLIQUE

- ▶  $k$  threshold (clique size);  $n$  vertices,  $m$  edges in graph

↪  $\binom{n}{k}$  candidates to check, each takes time  $O(k^2)$  to check

↪ Total time  $O(n^k \cdot k^2)$

## ▶ $p$ -VERTEXCOVER

- ▶  $k$  threshold (VC size);  $n$  vertices,  $m$  edges in graph

↪  $\binom{n}{k}$  candidates to check, each takes time  $O(m)$  to check

↪ Total time  $O(n^k \cdot m)$

## ▶ $p$ -GRAPHCOLORING

- ▶  $k$  threshold (#colors);  $n$  vertices,  $m$  edges in graph

↪  $k^n$  candidates to check, each takes time  $O(m)$

↪ Total time  $O(k^n \cdot m)$

# FPT Running Time

## Definition 4.7 (fpt-algorithm)

Let  $\kappa$  be a parameterization for  $\Sigma^*$ .

A (deterministic) algorithm  $A$  (with input alphabet  $\Sigma$ ) is a *fixed-parameter tractable algorithm* (*fpt-algorithm*) w.r.t.  $\kappa$  if its running time on  $x \in \Sigma^*$  with  $\kappa(x) = k$  is at most

$$f(k) \cdot p(|x|) = O(f(k) \cdot |x|^c)$$

where  $p$  is a polynomial of degree  $c$  and  $f$  is an **arbitrary** computable function. ◀

## Definition 4.8 (FPT)

A parameterized problem  $(L, \kappa)$  is *fixed-parameter tractable* if there is an fpt-algorithm that decides it.

The complexity class of all such problems is denoted by **FPT**. ◀

Intuitively, **FPT** plays the role of **P**.

# A First FPT Example

## Theorem 4.9 (p-variables-SAT is FPT)

*p-variables*-SAT  $\in$  FPT.

**Proof:**

Suffices to use brute force satisfiability for *p-variables*-SAT

---

```
1 procedure bruteForceSat( $\varphi, \mathcal{X} = \{x_1, \dots, x_k\}$ )
2   if  $k == 0$ 
3     if  $\varphi == \text{true}$  return  $\emptyset$  else UNSATISFIABLE
4   for value in  $\{\text{true}, \text{false}\}$  do
5      $A := \{x_1 \mapsto \text{value}\}$ 
6      $\psi := \varphi[x_1/\text{value}]$  // Substitute value for  $x_1$ 
7      $B := \text{bruteForceSat}(\psi, \{x_2, \dots, x_k\})$ 
8     if  $B \neq \text{UNSATISFIABLE}$ 
9       return  $A \cup B$ 
```

---

Worst case running time:  $O(2^k n)$  for  $n = |\varphi|$ .

$2^k$  recursive calls;

base case needs time  $O(|\phi|)$  to check whether formula evaluates to *true*

... but #variables not usually small

# Aren't we all FPT?

## Theorem 4.10 (k never decreases $\rightarrow$ FPT)

Let  $g : \mathbb{N} \rightarrow \mathbb{N}$  weakly increasing, unbounded and computable, and  $\kappa$  a parameterization with

$$\forall x \in \Sigma^* : \kappa(x) \geq g(|x|).$$

Then  $(L, \kappa) \in \text{FPT}$  for *any* decidable  $L$ .

$g$  weakly increasing:  $n \leq m \rightarrow g(n) \leq g(m)$

$g$  unbounded:  $\forall t \exists n : g(n) \geq t$

**Proof:**

# Aren't we all FPT? – Proof

Proof (cont.):

## Back to “sensible” parameters

- ↪ always check if parameter is reasonable (can be expected to be small)
  - ▶ if not, FPT might not even mean in NP!
- ▶ but now, for some positive examples!

## 4.2 Depth-Bounded Exhaustive Search I

# FPT Design Pattern

- ▶ The simplest FPT algorithms use exhaustive search
- ▶ but with a search tree bounded by  $f(k)$
- ▶ bruteforceSat was a typical example!
- ▶ does this work on other problems?

# Depth-Bounded Search for Vertex Cover

Let's try  $p$ -VERTEXCOVER.

Key insight: for every edge  $\{v, w\}$ , any vertex cover must contain  $v$  or  $w$

---

```
1 procedure simpleFptVertexCover( $G = (V, E), k$ ):
2   if  $E == \emptyset$  then return  $\emptyset$ 
3   if  $k == 0$  then return NOT_POSSIBLE // truncate search
4   Choose  $\{v, w\} \in E$  (arbitrarily)
5   for  $u$  in  $\{v, w\}$  do:
6      $G_u := (V \setminus \{u\}, E \setminus \{\{u, x\} \in E\})$  // Remove  $u$  from  $G$ 
7      $C_u := \text{simpleFptVertexCover}(G_u, k - 1)$ 
8   if  $C_v == \text{NOT\_POSSIBLE}$  then return  $C_w \cup \{w\}$ 
9   if  $C_w == \text{NOT\_POSSIBLE}$  then return  $C_v \cup \{v\}$ 
10  if  $|C_v| \leq |C_w|$  then return  $C_v \cup \{v\}$  else return  $C_w \cup \{w\}$ 
```

---

- ▶ Does not need explicit checks of solution candidates!
- ▶ runs in time  $O(2^k(n + m)) \rightsquigarrow$  fpt-algorithm for  $p$ -VERTEX-COVER

# Guessing the parameter

► Note: Previous algorithm only uses  $k$  to *truncate* branches.

↪ We can *guess* a  $k$  and it still works

↪ Try all  $k$ !

---

```
1 procedure vertexCoverBfs( $G = (V, E)$ )  
2   for  $k := 0, 1, \dots, |V|$  do  
3      $C := \text{simpleFptVertexCover}(G, k)$   
4     if  $C \neq \text{NOT\_POSSIBLE}$  return  $C$ 
```

---

► Running time:  $\sum_{k'=0}^k O(2^{k'}(n+m)) = O(2^k(n+m))$

↪ For exponentially growing cost, trying all values up to  $k$  costs only constant factor more

## 4.3 Problem Kernels

# Preprocessing

- ▶ Second key fpt technique are *reduction rules*
- ▶ **Idea:** Reduce the size of the instance (in polytime) without changing its outcome
- ▶ Trivial example for SAT:

If a CNF formula contains a single-literal clause  $\{x\}$  resp.  $\{\neg x\}$ , set  $x$  to *true* resp. *false* and remove the clause.

- ▶ doesn't do anything in the worst case ...
  - ▶ special case of resolution calculus rule 
$$\frac{a_1 \vee a_2 \vee \dots \vee x, \quad b_1 \vee b_2 \vee \dots \vee \neg x}{a_1 \vee a_2 \vee \dots \vee b_1 \vee b_2 \vee \dots}$$
  - ▶ basis of practical SAT solvers
  - ▶ Trivial example for VERTEXCOVER
- Remove vertices of degree 0 or 1. (never needed as part of optimal VC)
- ▶ Here: reduction rules that provably shrink an instance to size  $g(k)$

## Buss's Reduction Rule for VC

- ▶ Given a  $p$ -VERTEXCOVER instance  $(G, k)$

**"deg > k" Rule:** If  $G$  contains vertex  $v$  of degree  $\deg(v) > k$ , include  $v$  in potential solution and remove it from the graph.

- ▶ Can apply this simultaneously to degree  $> k$  vertices.
- ▶ Either rule applies, or all vertices bounded degree(!)

# Kernels

## Definition 4.11 (Kernelization)

Let  $(L, \kappa)$  be a parameterized problem. A function  $K : \Sigma^* \rightarrow \Sigma^*$  is *kernelization* of  $L$  w.r.t.  $\kappa$  if it maps any  $x \in L$  to an instance  $x' = K(x)$  with  $k' = \kappa(x')$  so that

1. (self-reduction)  $x \in L \iff x' \in L$
2. (polytime)  $K$  is computable in polytime.
3. (kernel-size)  $|x'| \leq g(k)$  for some computable function  $g$

We call  $x'$  the *(problem) kernel* of  $x$  and  $g$  the *size of the problem kernel*. ◀

# Buss's Kernel

**Buss's Reduction for Vertex Cover:** (repeatedly apply until no more changes)

- ▶  $\deg > k$  rule
- ▶ Remove degree 0 and 1 vertices

## Theorem 4.12 (Buss's Reduction is Kernelization)

Buss' reduction yields a kernelization for  $p$ -VERTEX-COVER with kernel size  $O(k^2)$ . ◀

### Proof:

After repeatedly applying Buss's rule as well as the isolated/leaf rule until neither applies further, we have  $\forall v \in V : 2 \leq \deg(v) \leq k$ .

(Note that the rule might reduce the parameter  $k$ ).

In the resulting graph, any VC of size  $\leq k$  covers  $\leq k^2$  edges.

If  $m > k^2$ , we output a trivial No-instance (e. g., a  $K_{k+1}$  a complete graph on  $k + 1$  vertices).

If  $m \leq k^2$ , then the input size is now bounded by  $g(k) = 2k^2$ . ■

# FPT iff Kernelization

## Theorem 4.13 (FPT $\leftrightarrow$ kernel)

A computable, parameterized problem  $(L, \kappa)$  is fixed-parameter tractable if and only if there is a kernelization for  $L$  w.r.t.  $\kappa$ .

**Proof:**

# FPT iff Kernelization [2]

Proof (cont.):

# Max-SAT Kernel

## Theorem 4.14 (Kernel for Max-SAT)

$p$ -MAX-SAT has a problem kernel of size  $O(k^2)$  which can be constructed in linear time. ◀

Proof:

◻

## Max-SAT Kernel [2]

### Proof (cont.):

# Max-SAT Kernel [3]

Proof (cont.):

**Corollary 4.15**

$p$ -MAX-SAT  $\in$  FPT

## 4.4 Depth-Bounded Search II: Planar Independent Set

## Deeper results (towards more shallow trees)

- ▶ Our previous examples of depth-bounded search were basically brute force
- ▶ Here we will see two more examples that exploit the problem structure in more interesting ways

# Independent Set on Planar Graphs

Recall: general problem  $p$ -INDEPENDENT-SET is  $\mathcal{W}[1]$ -hard.

## Definition 4.16 ( $p$ -PLANAR-INDEPENDENT-SET)

Given: a *planar* graph  $G = (V, E)$  and  $k \in \mathbb{N}$

Parameter:  $k$

Question:  $\exists V' \subset V : |V'| \geq k \wedge \forall u, v \in V' : \{u, v\} \notin E$  ?

## Theorem 4.17 (Depth-Bounded Search for Planar Independent Set)

$p$ -PLANAR-INDEPENDENT-SET is in FPT and can be solved in time  $O(6^k n)$ .

# Elementary Knowledge on Planar Graphs

## Theorem 4.18 (Euler's formula)

In any finite, connected planar graph  $G$  with  $n$  nodes,  $m$  edges  $f$  holds  $n - m + f = 2$ . ◀

## Corollary 4.19

A simple planar graph  $G$  on  $n \geq 3$  nodes has  $m \leq 3n - 6$  edges.

The average degree in  $G$  is  $< 6$ . ◀

# Depth-Bounded Search for Planar Independent Set

---

```
1 procedure planarIndependentSet( $G = (V, E)$ ,  $k$ ):
2   if  $k == 0$  then return  $\emptyset$ 
3   if  $k > |V|$  then return NOT_POSSIBLE // truncate search
4   Choose  $v \in V$  with minimal degree; let  $w_1, \dots, w_d$  be  $v$ 's neighbors
5   // By planarity, we know  $d \leq 5$ .
6   for  $u$  in  $\{v, w_1, \dots, w_d\}$  do
7      $D := \{u\} \cup N(u)$ 
8      $G_u := (V \setminus D, E \setminus \{\{x, y\} \in E : x \in D\})$  // Delete  $u$  and its neighbors
9      $I_u := \{u\} \cup \text{planarIndependentSet}(G_u, k - 1)$ 
10  return largest  $I_u$  or NOT_POSSIBLE if none exists
```

---

# Summary Planar Independent Set

- ▶ Note: INDEPENDENTSET is NP-hard on planar graphs even with vertex degrees at most 3
- ▶ planarIndependentSet will often be faster than  $O(6^k n)$
- ▶ works unchanged in  $O((d+1)^k n)$  time for any degeneracy- $d$  graph

every (induced) subgraph has vertex of degree at most  $d$

## 4.5 Depth-Bounded Search III: Closest String

# Closest String

## Definition 4.20 ( $p$ -CLOSEST-STRING)

Given: S set of  $m$  strings  $s_1, s_2, \dots, s_m$  of length  $L$  over alphabet  $\Sigma$  and a  $k \in \mathbb{N}$ .

Parameter:  $k$

Question: Is there a string  $s$  for which  $d_H(s, s_i) \leq k$  holds for all  $i = 1, \dots, m$ ? 

# Dirty Columns

## Definition 4.21 (Dirty Column)

A column of the  $m \times L$  matrix corresponding to  $m$  strings of length  $L$  is called *dirty* if it contains at least 2 different symbols. ◀

## Lemma 4.22 (Many Dirty Columns $\rightarrow$ No)

Let an instance to CLOSEST-STRING with  $m$  strings of length  $L$  and parameter  $k$  be given. If the corresponding  $m \times L$  matrix contains more than  $m \cdot k$  dirty columns, then no solution for the given instance exists. ◀

# Depth-Bounded Search for Closest String

---

```
1 procedure closestStringFpt( $s, d$ ):
2   if  $d < 0$  then return NOT_POSSIBLE
3   if  $d_H(s, s_i) > k + d$  for an  $i \in \{1, \dots, m\}$  then
4     return NOT_POSSIBLE
5   if  $d_H(s, s_i) \leq k$  for all  $i = 1, \dots, m$  then return  $s$ 
6   Choose  $i \in \{1, \dots, m\}$  arbitrarily with  $d_H(s, s_i) > k$ 
7    $P := \{p : s[p] \neq s_i[p]\}$ 
8   Choose arbitrary  $P' \subseteq P$  with  $|P'| = k + 1$ 
9   for  $p$  in  $P'$  do
10     $s' := s$ 
11     $s'[p] := s_i[p]$ 
12     $s_{ret} := \text{closestStringFpt}(s', d - 1)$ 
13    if  $s_{ret} \neq \text{NOT\_POSSIBLE}$  then return  $s_{ret}$ 
14  return NOT_POSSIBLE
```

---

► initial call  $\text{closestStringFpt}(s_1, k)$

# Too Much Dirt

## Lemma 4.23 (Pair Too Different $\rightarrow$ No)

Let  $S = \{s_1, s_2, \dots, s_m\}$  a set of strings and  $k \in \mathbb{N}$ . If there are  $i, j \in \{1, \dots, m\}$  with  $d_H(s_i, s_j) > 2k$ , then there is no string  $s$  with  $\max_{1 \leq i \leq m} d_H(s, s_i) \leq k$ .

# Depth-Bounded Search for Closest String

## Theorem 4.24 (Search Tree for Closest String)

There is a search tree of size  $O(k^k)$  for problem  $p$ -CLOSEST-STRING. ◀

## Corollary 4.25 (Closest String is FPT)

$p$ -CLOSEST-STRING can be solved in time  $O(mL + mk \cdot k^k)$ . ◀

- ▶ preprocessing ( $O(mL)$  time)

- ▶ ignore any clean columns

- ▶ reject if more than  $mk$  dirty columns

↪ effective string length after preprocessing is  $L' \leq mk$

- ▶ call `closestStringFpt( $s_1, k$ )`

- ▶ maintain  $d_H(s, s_i)$  in an array

- ↪ checking any distance  $d_H(s, s_i)$  takes  $O(1)$  time

- ▶ before and after recursive call, update array to reflect  $d_H(s', s_i)$

- Single character changed, so update only needs to check single position

- ↪ Can maintain distances in  $O(m)$  time per recursive call

- ▶  $P'$  can be computed in  $O(mk)$  time

## 4.6 Linear Recurrences & Better Vertex Cover

## A Better Algorithm for Vertex Cover

Recall: Branching on endpoints of  $k$  edges gives search space of size  $2^k$  for VERTEX-COVER.  
Can we do better?

**Idea:** Enlarge base case with “easy inputs”

Here: Consider graphs  $G$  with  $\deg(v) \leq 2$  for all  $v \in V(G)$ .

# Depth-Bounded Search for Vertex Cover

---

```
1 procedure betterFptVertexCover( $G = (V, E), k$ ):  
2   if  $E = \emptyset$  then return  $\emptyset$   
3   if  $k = 0$  then return NOT_POSSIBLE // truncate search  
4   if all node have degree  $\leq 2$  then  
5     Find connected components of  $G$   
6     for each component  $G_i$  do  
7       Fill  $C_i$  by picking every other node,  
8       starting with the neighbor of a degree-one node if one exists  
9      $C := \bigcup C_i$   
10    if  $|C| \leq k$  then return  $C$  else return NOT_POSSIBLE  
11    Choose  $v$  with maximal degree, let  $w_1, \dots, w_d$  be its neighbors //  $d \geq 3$   
12    For  $D$  in  $\{\{v\}, \{w_1, \dots, w_d\}\}$  do:  
13       $G_D := (V \setminus D, E \setminus \{\{x, y\} \in E : x \in D\})$  // Remove  $D$  from  $G$   
14       $C_D := D \cup \text{betterFptVertexCover}(G_D, k - |D|)$   
15    return smallest  $C_D$  or NOT_POSSIBLE if none exists
```

---

*How to analyze running time of betterFptVertexCover?*

# Analysis of betterFptVertexCover

worst case running time

- ▶ never have all degrees  $\leq 2$
- ▶ always need both recursive calls (until base case)
- ▶ ignore that graph gets smaller

$$T_0 = \Theta(1)$$

$$T_k = \Theta(|V| + |E|) + T_{k-3} + T_{k-1}$$

If we only number of base cases  $B_n$ , we obtain  $T_n = O(B_n n^2)$

$$B_0 = 1, B_1 = 1, B_2 = 1$$

$$B_k = B_{k-3} + B_{k-1} \quad (k \geq 3)$$

# Solving Linear Recurrences

# Solving Linear Recurrences – Result

## Theorem 4.26 (Linear Recurrences)

Let  $d_1, \dots, d_i \in \mathbb{N}$  and  $d = \max d_j$ .

The solution to the *homogeneous linear recurrence equation*

$$T_n = T_{n-d_1} + T_{n-d_2} + \dots + T_{n-d_i}, \quad (n \geq d)$$

is always given by

$$T_n = \sum_{\ell} \sum_{j=0}^{\mu_{\ell}-1} c_{\ell,j} z_{\ell}^n n^j$$

where we sum over all roots  $z_{\ell}$  of multiplicity  $\mu_{\ell}$  of the so-called *characteristic polynomial*  $z^d - z^{d-d_1} - z^{d-d_2} \dots - z^{d-d_i}$ .

The  $d$  coefficients  $c_{\ell,j}$  are determined by the  $d$  initial values  $T_0, T_1, \dots, T_{d-1}$ . ◀

## Corollary 4.27

$T_n = O(z_0^n n^d)$  for  $z_0$  the root of the characteristic polynomial with *largest absolute value*. ◀

## Analysis of betterFptVertexCover [2]

$$T_0 = \Theta(1)$$

$$T_k = \Theta(|V| + |E|) + T_{k-3} + T_{k-1}$$

If we only number of base cases  $B_n$ , we obtain  $T_n = O(B_n n^2)$

$$B_0 = 1, B_1 = 1, B_2 = 1$$

$$B_k = B_{k-3} + B_{k-1} \quad (k \geq 3)$$

$\rightsquigarrow \vec{d} = (1, 3)$ ; characteristic polynomial  $z^3 - z^2 - 1$   
roots at  $z_0 \approx 1.4656$  and  $z_{1,2} \approx -0.2328 \pm 0.7926i$

### Theorem 4.28 (Depth-Bounded Search for Vertex Cover)

$p$ -VERTEX-COVER can be solved in time  $O(1.4656^k n^2)$ .

## 4.7 Interleaving

# Motivation

Up to now, considered two-phase algorithms

1. Reduction to problem kernel
2. Solve kernel by depth-bounded exhaustive search

Idea: Apply kernelization *in each recursive step*.

## (Extreme) Example: Vertex Cover with large-degree rule

- ▶ As a (slightly artificial) example, consider only using the simple reduction rule

**“ $\deg > k$ ” Rule:** If  $G$  contains vertex  $v$  of degree  $\deg(v) > k$ , include  $v$  in potential solution and remove it from the graph.

- ▶ **Algorithm A:**

1. Apply  $\deg > k$  rule until saturation
2. Call `simpleFptVertexCover` (recursively branch over arbitrary edge)

- ▶ **Algorithm B:** Same, interleaved:

- ▶ Modified `simpleFptVertexCover`
- ▶ Before choosing each new edge to branch on, apply  $\deg > k$  rule.

# SimpleFptVertexCover Interleaved

---

```
1 procedure simpleFptVertexCover( $G = (V, E)$ ,  $k$ ):
2   if  $E == \emptyset$  then return  $\emptyset$ 
3   if  $k == 0$  then return NOT_POSSIBLE
4   // nothing
5   // new
6   // on
7   // this
8   // side
9   Choose  $\{v, w\} \in E$  (arbitrarily)
10  for  $u$  in  $\{v, w\}$  do:
11     $G_u := G[V \setminus \{u\}]$ 
12     $C_u := \text{simpleFptVertexCover}(G_u, k - 1)$ 
13  if  $C_v == \text{NOT\_POSSIBLE}$  then return  $C_w \cup \{w\}$ 
14  if  $C_w == \text{NOT\_POSSIBLE}$  then return  $C_v \cup \{v\}$ 
15  if  $|C_v| \leq |C_w|$  then
16    return  $C_v \cup \{v\}$ 
17  else
18    return  $C_w \cup \{w\}$ 
```

---

---

```

# Comparison on Lollipop Flowers

Consider family of graphs  $G_k$  “Lollipop Flowers”:

“head” vertex with  $k - 2$  stars of  $k - 2$  leaves each attached + “tail” of  $3k + 1$  vertex path

$$n = |V(G_k)| = (k - 2)(k - 1) + 1 + 3k + 1 = k^2 + 4$$

## Algorithm A

$\deg > k$  rule does nothing

search space remains  $2^k$

Answer No after exploring all branches

$\rightsquigarrow$  time  $\Theta(2^k k^2)$

## Algorithm B

initially same (no reduction)

after 2 edges removed from tail, parameter  $k - 2$

vertices in head have degree  $k - 1$

Output No (parameter 0, but tail edges left)

$\rightsquigarrow$  time  $\Theta(k^2)$

# Setting for Interleaving

*Can we prove a general speedup?*

**Assumptions:** (more restrictive than general kernelization!)

- ▶  $K$  kernelization that
  - ▶ produces *kernel of size*  $\leq q(k)$  for  $q$  a *polynomial*
  - ▶ in time  $\leq p(n)$  for  $p$  a polynomial
- ▶ Branch in depth-bounded search tree
  - ▶ into  $i$  subproblems with branching vector  $\vec{d} = (d_1, \dots, d_i)$   
(i. e., parameter in subproblems  $k - d_1, \dots, k - d_i$ )
  - ▶ Branching is computed in time  $\leq r(n)$  for  $r$  a polynomial

$\rightsquigarrow$  search space has size  $O(\alpha^k)$ .

$\rightsquigarrow$  Running time of two-phase approach on input  $x$  with  $n = |x|$  and  $k = \kappa(x)$ :

$$O\left(p(n) + r(q(k)) \cdot \alpha^k\right)$$

# With Interleaving

Generic interleaving:

---

```
1 if  $|I| > c \cdot q(k)$  then  
2    $(I, k) := (I', k')$  where  $(I', k')$  forms a problem kernel // Conditional Reduction  
3 end  
4 replace  $(I, k)$  with  $(I_1, k - d_1), (I_2, k - d_2), \dots, (I_i, k - d_i)$  // Branching
```

---

$\rightsquigarrow$  Running time of interleaved approach on input  $x$  with  $n = |x|$  and  $k = \kappa(x)$  is at most  $T_k$ :

$$T_\ell = T_{\ell-d_1} + \dots + T_{\ell-d_i} + p(q(\ell)) + r(q(\ell))$$

Compare to non-interleaved version:

$$T_\ell = T_{\ell-d_1} + \dots + T_{\ell-d_i} + r(q(k))$$

Here the inhomogeneous term is constant w.r.t.  $\ell$ , but depends on  $k$

$\rightsquigarrow$  cannot ignore constant factors

# Analysis of interleaved betterFptVertexCover [1]

Consider betterFptVertexCover from before, but with  $\text{deg} > k$  rule added.

- ▶ Initial call has unbounded  $n$  and  $m$ ; after applying degree 0, 1,  $> k$  rules (in  $O(n + m)$  time) size of graph  $n + m = O(k^2)$
- ▶ interleaving  $\rightsquigarrow$  graph also bounded recursively (in terms of new  $k$ )
- ▶ Recursive worst-case time after first reduction:  
 $T_0 = \Theta(1)$   
 $T_k = O(k^2) + T_{k-3} + T_{k-1}$

# Inhomogenous Linear Recurrences

# Inhomogenous Linear Recurrences Summary

## Theorem 4.29 (Linear Recurrences II)

Let  $d_1, \dots, d_i \in \mathbb{N}$  and  $d = \max d_j$ .

Consider the *inhomogeneous linear recurrence equation*

$$T_n = T_{n-d_1} + T_{n-d_2} + \dots + T_{n-d_i} + \textcolor{red}{f_n}, \quad (n \geq d)$$

with  $(f_n)_{n \in \mathbb{R}_{>0}}$  a known sequence of positive numbers, satisfying  $f_n = O(n^c)$  and  $d$  initial values  $T_0, \dots, T_{d-1} \in \mathbb{R}_{>0}$ .

Let  $z_0$  be the root with largest absolute value of  $z^d - \sum_{j=1}^i z^{d-d_j}$  and assume  $f_n = O((z - \varepsilon)^n)$  for some fixed  $\varepsilon > 0$ .

Then  $T_n = O(T_n^0)$  where  $T_n^0$  is defined as  $T_n$  with  $f_n \equiv 0$ .

# A Little Excursion: Singularity Analysis

**General strategy:** use generating functions for asymptotic approximations

## Sequence Land

▶ number sequence  $(a_n)_{n \geq 0}$

▶ recurrence equation

▶ closed form for  $a_n$

▶ *asymptotic* approximation  
 $a_n = z_0^{-n} n^{\alpha-1} (1 \pm O(n^{-1}))$

## Generating Function Land

▶ (ordinary) generating function  $A(z) = \sum_{n \geq 0} a_n z^n$

▶ (functional) equation for  $A(z)$

↓ solve, simplify (e. g., partial fractions)

↪ closed form for  $A(z)$

▶ exact coefficients  $[z^n]A(z)$

OR approximate  $A(z)$   
near its *dominant singularity*

↪ *singular expansion* at  $z = z_0$   
 $A(z) = f(z) \pm O((1 - z/z_0)^{-\alpha})$

←  
transfer thms

# O-Transfer

## Theorem 4.30 (Transfer-Theorem of Singularity Analysis)

Assume  $f(z)$  is  $\Delta$ -analytic and admits the singular expansion

$$f(z) = g(z) \pm O((1-z)^{-\alpha}) \quad (z \rightarrow 1)$$

with  $\alpha \in \mathbb{R}$ . Then

$$[z^n]f(z) = [z^n]g(z) \pm O(n^{\alpha-1}) \quad (n \rightarrow \infty).$$

## Possible Extensions

- ▶ (constant) coefficients  $c_j \cdot T_{n-d_j}$  in recurrence  
 $\rightsquigarrow$  different characteristic polynomial, same ideas
- ▶ *any* recurrence that leads to a representation of the generating function as a *singular expansion* around the dominant singularity.

$$\begin{aligned} f(z) &= c(1 - z/z_0)^{-m} \pm O((1 - z/z_0)^{-m+1}) \quad (z \rightarrow z_0) \\ \rightsquigarrow [z^n] f(z) &= \frac{c}{(m-1)!} z_0^{-n} n^{m-1} \cdot \left(1 \pm O(n^{-1})\right) \quad (n \rightarrow \infty) \end{aligned}$$

- ▶ other powers  $\alpha$  in  $1/(1 - z)^\alpha$ :

$$[z^n] \frac{1}{(1 - \frac{z}{z_0})^\alpha} = \frac{z_0^{-n} n^{\alpha-1}}{\Gamma(\alpha)} \left(1 \pm O(n^{-1})\right) \quad (n \rightarrow \infty) \quad \begin{array}{l} -\alpha \notin \mathbb{N}_0 \\ z_0 > 0 \end{array}$$

- ▶ much more!  $\rightsquigarrow$  *analytic combinatorics*

## Analysis of interleaved betterFptVertexCover [2]

►  $T_0 = \Theta(1)$

$$T_k = O(k^2) + T_{k-3} + T_{k-1}$$

$\rightsquigarrow T_k = O(1.4656^k)$  (same characteristic polynomial)

► Total time:  $O(1.4656^k + n + m)$

► The current record is  $O(1.2738^k + kn)$  time

# Summary

- ▶ Strategies for fpt algorithms
  - ▶ Use parameter to bound depth of exhaustive search
  - ▶ Use problem specific reduction rules to shrink input  $\rightsquigarrow$  kernel(ization)s
- ▶ analysis of exact exponential searches often reduces to linear recurrences
  - ▶ generating functions!
- ▶ more clever branching reduces exponent of search space
- ▶ interleaving kernelization and exhaustive search improves polynomial parts
